#### C++26 Reflection for JSON Serialization

#### **A Practical Journey**

- Daniel Lemire, *University of Quebec*
- Francisco Geiman Thiesen, Microsoft

CppCon 2025

#### **JSON**

- Portable, simple
- Douglas Crockford (2001)
- RFC 8259 (December 2017)

#### **JSON**

- scalar values
  - strings (controls and quotes must be escaped)
  - o numbers (but not NaN or Inf)
  - o true, false, null
- composed values
  - objects (key/value)
  - arrays (list)

```
"username": "Alice",
  "level": 42,
  "health": 99.5,
  "inventory": ["sword", "shield", "potion"]
}
```

#### **JSON** downside?

JSON can be *slow*. E.g., 20 MB/s.

Much slower than disk or network

# Micron shows off world's fastest PCIe 6.0 SSD, hitting 27 GB/s speeds — Astera Labs PCIe 6.0 switch enables impressive sequential reads

By Sunny Grimm published March 8, 2025

The next-gen of networking and storage is hitting the trade shows

#### **Performance**

- simdjson was the first library to break the gigabyte per second barrier
  - Parsing Gigabytes of JSON per Second, VLDB Journal 28 (6), 2019
  - o On-Demand JSON: A Better Way to Parse Documents? SPE 54 (6), 2024
- JSON for Modern C++ can be  $100\times$  slower!

# **Usage**

The simdjson library is found in...

- Node.js
- ClickHouse
- Velox

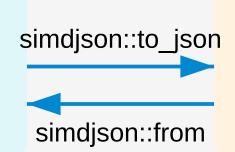

# Automate the serialization/deserialization process.

#### **Player Class**

name: "Alice"

score: 100

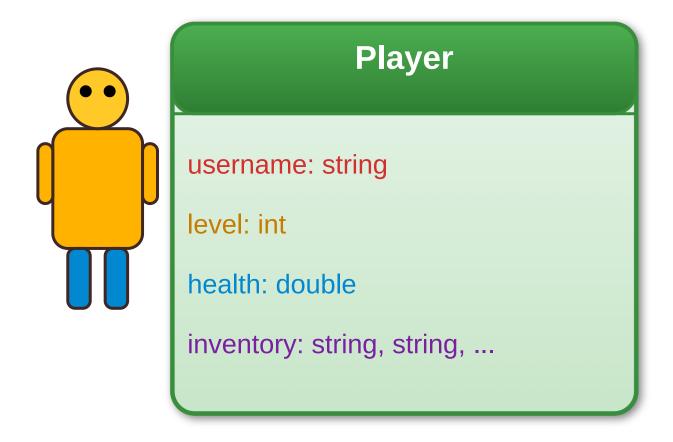

#### **JSON**

{ "name": "Alice", "score": 100 }

### **The Problem**

Imagine you're building a game server that needs to persist player data.

#### You start simple:

```
struct Player {
    std::string username;
    int level;
    double health;
    std::vector<std::string> inventory;
};
```

# The Traditional Approach: Manual Serialization

Without reflection, you may write this tedious code:

```
// Serialization - converting Player to JSON
fmt::format(
        "\"username\":\"{}\","
        "\"level\":{},"
        "\"health\":{},"
        "\"inventory\":{}"
        "}}",
        escape_json(p.username),
        p.level,
        std::isfinite(p.health) ? p.health : -1.0,
        p.inventory| std::views::transform(escape_json)
);
```

# With a library (JSON for Modern C++)

Or you might use a library.

# **Manual Deserialization (simdjson)**

```
object obj = val.get_object();
p.username = obj["username"].get_string();
p.level = obj["username"].get_int64();
p.health = obj["health"].get_double();
array arr = obj["inventory"].get_array();
for (auto item : arr) {
   p.inventory.emplace_back(item.get_string());
}
```

#### **The Pain Points**

This manual approach has several problems:

- 1. **Repetition**: Every field needs to be handled twice (serialize + deserialize)
- 2. Maintenance Nightmare: Add a new field? Update both functions!
- 3. **Error-Prone**: Typos in field names, forgotten fields, type mismatches
- 4. **Boilerplate Explosion**: 30+ lines for a simple 4-field struct
- 5. **Performance**: You may fall into performance traps

#### When Your Game Grows...

```
struct Equipment {
    std::string name;
    int damage; int durability;
};
struct Achievement {
    std::string title; std::string description; bool unlocked;
    std::chrono::system_clock::time_point unlock_time;
};
struct Player {
    std::string username;
    int level; double health;
    std::vector<std::string> inventory;
    std::map<std::string, Equipment> equipped;
                                              // New!
                                          // New!
    std::vector<Achievement> achievements;
    std::optional<std::string> guild_name;
                                          // New!
};
```

#### The Solution: C++26 Static Reflection

With C++26 reflection and simdjson, all that boilerplate disappears:

```
// Just define your struct - no extra code needed!
struct Player {
    std::string username;
    int level;
    double health;
    std::vector<std::string> inventory;
    std::map<std::string, Equipment> equipped;
    std::vector<Achievement> achievements;
    std::optional<std::string> guild_name;
};
```

#### **Automatic Serialization**

```
// Serialization - one line!
void save_player(const Player& p) {
   std::string json = simdjson::to_json(p); // That's it!
   // Save json to file...
}
```

#### **Automatic Deserialization**

```
// Deserialization - one line!
Player load_player(const std::string& json_str) {
    return simdjson::from<Player>(json_str); // That's it!
}
```

- No manual field mapping
- No maintenance burden
- Handles nested structures automatically
- Performance tuned by the library

# **Python**

```
# Python
import json
json_str = json.dumps(player.__dict__)
player = Player(**json.loads(json_str))
```

# **Python reflection**

```
def inspect_object(obj):
    print(f"Class name: {obj.__class__.__name__}")
    for attr, value in vars(obj).items():
        print(f" {attr}: {value}")
```

#### Go

```
jsonData, err := json.MarshalIndent(player, "", " ")
if err != nil {
        log.Fatalf("Error during serialization: %v", err)
}
var deserializedPlayer Player
err = json.Unmarshal([]byte(jsonStr), &deserializedPlayer)
```

#### Go reflection

Runtime reflection only

```
typ := reflect.TypeOf(obj)
for i := 0; i < typ.NumField(); i++ {
    field := typ.Field(i)
}</pre>
```

#### Java and C#

```
string jsonString = JsonSerializer.Serialize(player, options);
Player deserializedPlayer = JsonSerializer.Deserialize<Player>(jsonInput, options);
```

#### Java and C# reflection

• Runtime reflection only.

```
Class<?> playerClass = Player.class;
Object playerInstance = playerClass.getDeclaredConstructor().newInstance();
Field nameField = playerClass.getDeclaredField("name");
```

# Rust (serde)

```
// Rust with serde
let json_str = serde_json::to_string(&player)?;
let player: Player = serde_json::from_str(&json_str)?;
```

#### **Rust reflection**

- Rust does not have ANY introspection.
- You cannot enumerate the methods of a struct. Either at runtime or at compiletime.
- Rust relies on annotation (serde) followed by re-parsing of the code.

# Reflection as accessing the attributes of a struct.

language	runtime reflection	compile-time reflection
C++ 26	2	
Go		<b>2</b>
Java		<b>2</b>
C#		<u></u>
Rust	<b>2</b>	<b>2</b>

# With C++26: simple, maintainable, performant code

```
std::string json_str = simdjson::to_json(player);
Player player = simdjson::from<Player>(json_str);
```

- AT COMPILE TIME
- with no extra tooling
- no annotation

#### **How Does It Work?**

#### The Key Insight: Compile-Time Code Generation

"How can compile-time reflection handle runtime JSON data?"

The answer: Reflection operates on types and structure, not runtime values.

It generates regular C++ code at compile time that handles your runtime data.

## What Happens Behind the Scenes

```
// What you write:
Player p = simdjson::from<Player>(runtime_json_string);
// What reflection generates at COMPILE TIME (conceptually):
Player deserialize_Player(const json& j) {
    Player p;
    p.username = j["username"].get<std::string>();
    p.level = j["level"].get<int>();
    p.health = j["health"].get<double>();
    p.inventory = j["inventory"].get<std::vector<std::string>>();
    // ... etc for all members
    return p;
```

# The Actual Reflection Magic

```
template <typename T>
  requires(std::is_class_v<T>) // For user-defined types
error_code deserialize(auto& json_value, T& out) {
    simdjson::ondemand::object obj;
    SIMDJSON_TRY(json_value.get_object().get(obj));
   // This [:expand:] happens at COMPILE TIME
    // It literally generates code for each member
    [:expand(std::meta::nonstatic_data_members_of(^^T)):] >> [&]<auto member>() {
        // These are compile-time constants
        constexpr std::string_view field_name = std::meta::identifier_of(member);
        constexpr auto member_type = std::meta::type_of(member);
       // This generates code for each member
        auto err = obj[field_name].get(out.[:member:]);
        if (err && err != simdjson::NO_SUCH_FIELD) {
            return err;
    return simdjson::SUCCESS;
```

# The [:expand:] Statement

The [:expand:] statement is the key:

- It's like a compile-time for-loop
- Generates code for each struct member
- By the time your program runs, all reflection has been "expanded" into normal C++ code

#### This means:

- Zero runtime overhead
- Full optimization opportunities
- Type safety at compile time

# Compile-Time vs Runtime: What Happens When

```
struct Player {
   std::string username; // ← Compile-time: reflection sees this
                  // ← Compile-time: reflection sees this
   int level;
   double health; // ← Compile-time: reflection sees this
};
// COMPILE TIME: Reflection reads Player's structure and generates:
// - Code to read "username" as string
// - Code to read "level" as int
// - Code to read "health" as double
// RUNTIME: The generated code processes actual JSON data
std::string json = R"({"username":"Alice","level":42,"health":100.0})";
Player p = simdjson::from<Player>(json);
// Runtime values flow through compile-time generated code
```

# Compile-Time Safety: Catching Errors Before They Run

```
// X COMPILE ERROR: Type mismatch detected
struct BadPlayer {
    int username; // Oops, should be string!
};
// simdjson::from<BadPlayer>(json) won't compile if JSON has string
// X COMPILE ERROR: Non-serializable type
struct InvalidType {
    std::thread t; // Threads can't be serialized!
};
// simdjson::to_json(InvalidType{}) fails at compile time
// ✓ COMPILE SUCCESS: All types are serializable
struct GoodType {
    std::vector<int> numbers;
    std::map<std::string, double> scores;
    std::optional<std::string> nickname;
```

# **Zero Overhead: Why It's Fast**

Since reflection happens at compile time, there's no runtime penalty:

- 1. No runtime type inspection everything is known at compile time
- 2. No string comparisons for field names they become compile-time constants
- 3. Optimal code generation the compiler sees the full picture
- 4. Inline everything generated code can be fully optimized

The generated code is often **faster than hand-written code** because:

- It's consistently optimized
- No human errors or inefficiencies
- Leverages simdjson's SIMD parsing throughout

#### **Performance: The Best Part**

You might think "automatic = slow", but with simdjson + reflection:

- Compile-time code generation: No runtime overhead from reflection
- SIMD-accelerated parsing: simdjson uses CPU vector instructions
- Zero allocation: String views and in-place parsing
- Throughput: ~2-4 GB/s on modern hardware

The generated code is often *faster* than hand-written code!

#### **Real-World Benefits**

#### Before Reflection (Our Game Server example)

- 1000+ lines of serialization code
- Prone to bugs due to serialization mismatching
- Adding new features can imply making tedious changes to boilerplate serialization code

#### **After Reflection**

- **0 lines** of serialization code
- **0 serialization bugs** (if it compiles, it works!)
- New features can be added much faster

# The Bigger Picture

This pattern extends beyond games:

- **REST APIs**: Automatic request/response serialization
- Configuration Files: Type-safe config loading
- Message Queues: Serialize/deserialize messages
- Databases: Object-relational mapping
- RPC Systems: Automatic protocol generation

With C++26 reflection, C++ finally catches up to languages like Rust (serde), Go (encoding/json), and C# (System.Text.Json) in terms of ease of use, but with **better performance** thanks to simdjson's SIMD optimizations.

# **Try It Yourself**

```
struct Meeting {
    std::string title;
    std::chrono::system_clock::time_point start_time;
    std::vector<std::string> attendees;
    std::optional<std::string> location;
    bool is_recurring;
};
// Automatically serializable/deserializable!
std::string json = simdjson::to_json(Meeting{
    .title = "CppCon Planning",
    .start_time = std::chrono::system_clock::now(),
    .attendees = {"Alice", "Bob", "Charlie"},
    .location = "Denver",
    .is_recurring = true
});
Meeting m = simdjson::from<Meeting>(json);
```

# **Round-Trip Any Data Structure**

```
struct TodoItem {
    std::string task;
    bool completed;
    std::optional<std::string> due_date;
};
struct TodoList {
    std::string owner;
    std::vector<TodoItem> items;
    std::map<std::string, int> tags; // tag -> count
};
// Serialize complex nested structures
TodoList my_todos = { /* ... */ };
std::string json = simdjson::to_json(my_todos);
// Deserialize back - perfect round-trip
TodoList restored = simdjson::from<TodoList>(json);
assert(my_todos == restored); // Works if you define operator==
```

#### The Entire API Surface

Just two functions. Infinite possibilities.

```
simdjson::to_json(object) // → JSON string
simdjson::from<T>(json) // → T object
```

That's it.

No macros. No code generation. No external tools.

Just simdjson leveraging C++26 reflection.

# **Supporting Standard Containers**

Through concepts and template specialization, we support:

- std::vector<T>, std::array<T, N>
- std::map<K, V>, std::unordered\_map<K, V>
- std::optional<T>
- std::variant<Types...>
- And many more...

All work seamlessly with reflection!

#### Conclusion

#### C++26 Reflection + simdjson =

- Zero boilerplate
- **Compile-time** safety
- **V** Blazing fast performance
- **Clean, modern API**

Welcome to the future of C++ serialization!
